Section 4.1: Numerical Differentiation

Main Idea: To derive formulas for numerical differentiation, we start with a Lagrange interpolating polynomial such that $f(x) = \sum_{j=0}^n f(x_j)L_j(x) + \frac{(x-x_0)(x-x_1)\cdots(x-x_n)}{(n+1)!}f^{(n+1)}(z(x))$. We differentiate this expression, and observe what happens when we evaluate $f(x)$ when $x = x_k$ (one of the values our interpolating polynomial is based upon). This gives us both an approximation formula for the derivative $f'(x_k)$ and an expression for the error in this approximation in terms of $f^{(n+1)}(z(x_k))$.

The two point approximation formula:

$$f'(x_0) = \frac{f(x_0+h) - f(x_0)}{h} - \frac{h}{2}f''(z_0)$$

Three point approximation formulas:

$$f'(x_0) = \frac{1}{2h} [-3f(x_0) + 4f(x_0+h) - f(x_0+2h)] - \frac{h^2}{3}f'''(z_0)$$

$$f'(x_0) = \frac{1}{2h} [-f(x_0-h) + f(x_0+h)] - \frac{h^2}{6}f'''(z_1)$$

$$f'(x_0) = \frac{1}{2h} [f(x_0-2h) - 4f(x_0-h) + 3f(x_0)] + \frac{h^2}{3}f'''(z_2)$$

Some five point approximation formulas:

$$f'(x_0) = \frac{1}{12h} [f(x_0-2h) - 8f(x_0-h) + 8f(x_0+h) - f(x_0+2h)] + \frac{h^4}{30}f^{(5)}(z)$$

$$f'(x_0) = \frac{1}{12h} [-25f(x_0) + 48f(x_0+h) - 36f(x_0+2h) + 16f(x_0+3h) - 3f(x_0+4h)] + \frac{h^4}{5}f^{(5)}(z)$$

Example: Suppose that we have the following data:

x	0.78	0.79	0.80	0.81	0.82
$f(x) = \tan x$	0.9892615369	1.009246288	1.029638557	1.050455142	1.071713723

We wish to approximate $f'(0.80)$. Notice that in this table, $h = 0.01$. Also, if we wish to compute upper bounds on the error in our approximations, we will need to compute several derivatives of $f(x) = \tan x$.

$$f'(x) = \sec^2 x. \quad f''(x) = 2 \sec^2(x) \tan(x). \quad f'''(x) = 4 \sec^2(x) \tan^2(x) + 2 \sec^4(x)$$

$$f^{(4)}(x) = 8 \sec^2(x) \tan^3(x) + 16 \sec^4(x) \tan(x),$$

$$\text{and } f^{(5)}(x) = 16 \sec^2(x) \tan^4(x) + 88 \sec^4(x) \tan^2(x) + 16 \sec^6(x)$$

Recall that both $\tan x$ and $\sec x$ are positive and increasing on the interval $[0, \frac{\pi}{2})$. Therefore, the maxima of the derivatives of $f(x)$ will occur at the right hand endpoint of the interval in question (assuming h is sufficiently small).

One Point Approximations:

- A Backwards Estimate: $f'(x_0) \approx \frac{f(0.79) - f(.80)}{-0.01} = \frac{1.009246288 - 1.029638557}{-.01} \approx 2.0392269$
- *Error Bound:* $\frac{h}{2} f''(z_0) \leq \frac{0.01}{2} f''(.80) \approx 0.02121215597$
- A Forward Estimate: $f'(x_0) \approx \frac{f(0.81) - f(0.80)}{0.01} = \frac{1.050455142 - 1.029638557}{.01} \approx 2.0816585$
- *Error Bound:* $\frac{h}{2} f''(z_0) \leq \frac{0.01}{2} f''(.81) \approx 0.02209586179$

Three Point Approximations:

- A Forward Estimate: $f'(x_0) \approx \frac{1}{2(.01)} [-3f(.80) + 4f(.81) - f(.82)]$
 $= \frac{1}{.02} [-3(1.029638557) + 4(1.050455142) - (1.071713723)] \approx 2.05955865$
- *Error Bound:* $\frac{h^2}{3} f'''(z_0) \leq \frac{(.01)^2}{3} f'''(.82) \approx 0.0006367948289$
- A “Middle” Estimate: $f'(x_0) \approx \frac{1}{2(0.01)} [-f(.79) + f(.81)]$
 $= \frac{1}{.02} [-(1.009246288) + (1.050455142)] \approx 2.06044270$
- *Error Bound:* $\frac{h^2}{6} f'''(z_0) \leq \frac{(.01)^2}{6} f'''(.81) \approx 0.0003022223166$
- A Backwards Estimate: $f'(x_0) \approx \frac{1}{2(.01)} [f(.78) - 4f(.79) + 3f(.80)]$
 $= \frac{1}{.02} [(0.9892615369) - 4(1.009246288) + 3(1.029638557)] \approx 2.0596028$
- *Error Bound:* $\frac{h^2}{3} f'''(z_0) \leq \frac{(.01)^2}{3} f'''(.80) \approx 0.0005741607773$

A Five Point Approximation:

- A “Middle” Estimate: $f'(x_0) \approx \frac{1}{12(.01)} [f(.78) - 8f(.79) + 8f(.81) - f(.82)]$
 $= \frac{1}{.12} [(0.9892615369) - 8(1.009246288) + 8(1.050455142) - (1.071713723)] \approx 2.060155379$
- *Error Bound:* $\frac{h^4}{30} f^{(5)}(z_0) \leq \frac{(.01)^4}{30} f^{(5)}(.82) \approx 2.235473421 \times 10^{-7}$

Notice that we do not have all of the data values needed to use the other 5 point estimate at $x = 0.80$.
