

Properties of the Definite Integral

Definite Integrals

Approximating Area Using Partitions:

Given a function f on an interval $[a, b]$, we can approximate area using partitions that do not necessarily have rectangles all of the same width. A *partition* P of the interval $[a, b]$ of size n is a set of numbers $a = x_0 < x_1 < x_2 < \dots < x_{n-1} < x_n = b$. $\Delta x_k = x_k - x_{k-1}$ is the width of the k th subinterval, and $\|P\|$, the *norm* of the partition P , is the width of the widest of all the subintervals in P .

The *Riemann sum* of f on $[a, b]$ for a partition P is $R_P = \sum_{k=1}^n f(w_k)\Delta x$, where w_k is some point in the k th subinterval of the partition P .

If $\lim_{\|P\| \rightarrow 0} \sum_{k=1}^n f(w_k)\Delta x = L$ for some real number L , then we say that f is integrable on $[a, b]$, and the definite integral of f on $[a, b]$ is:

$$\int_a^b f(x)dx = \lim_{\|P\| \rightarrow 0} \sum_{k=1}^n f(w_k)\Delta x = L$$

The Fundamental Theorem of Calculus:

Let f be a continuous function on the interval $[a, b]$:

- (a) If G is the function defined by $\int_a^x f(t) dt$ for every x in $[a, b]$, then G is an antiderivative of f on $[a, b]$.
 (b) If F is any antiderivative of f on $[a, b]$, then:

$$\int_a^b f(x) dx = F(b) - F(a)$$

Example: $\int_1^3 3x^2 dx = x^3 \Big|_1^3 = 3^3 - 1^3 = 27 - 1 = 26$

Properties of Definite Integrals

$$1. \int_a^b c \, dx = c(b - a)$$

$$2. \int_a^a f(x) \, dx = 0$$

$$3. \int_a^b f(x) \, dx = - \int_b^a f(x) \, dx$$

$$4. \int_a^b cf(x) \, dx = c \int_a^b f(x) \, dx, \text{ for any constant } c$$

$$5. \int_a^b f(x) \pm g(x) \, dx = \int_a^b f(x) \, dx \pm \int_a^b g(x) \, dx$$

$$6. \int_a^b f(x) \, dx = \int_a^c f(x) \, dx + \int_c^b f(x) \, dx$$

$$7. \text{ If } f \text{ is integrable on } [a, b] \text{ and } f(x) \geq 0 \text{ for every } x \text{ in } [a, b], \text{ then } \int_a^b f(x) \, dx \geq 0$$

$$8. \text{ If } f \text{ and } g \text{ are integrable on } [a, b] \text{ and } f(x) \geq g(x) \text{ for every } x \text{ in } [a, b], \text{ then } \int_a^b f(x) \, dx \geq \int_a^b g(x) \, dx$$

The Mean Value Theorem for Definite Integrals:

If f is continuous on $[a, b]$, then there is a number z in the open interval (a, b) such that

$$\int_a^b f(x) \, dx = f(z)(b - a)$$

The Average Value of a Function

Let f be a function that is integrable on an interval $[a, b]$. Then the **average value** of f over $[a, b]$ is

$$\frac{1}{b - a} \int_a^b f(x) \, dx.$$
