Chem 350 Jasperse Ch. 10 Notes

#### 10.1,2 Intro, Classification

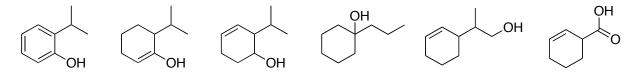

"<u>Alcohol</u>": OH attached to a saturated, sp<sup>3</sup>, "alkyl" carbon

"Enol" or "vinyl alcohol": OH attached to an alkene

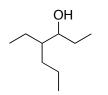

OH enol or vinyl alcohol

Problem: Classify each of the following either as a phenol, as a carboxylic acid, or as a 1°, 2°, 3°, or vinyl alcohol:

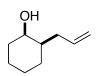

10.3 Nomenclature

- A. IUPAC, when alcohol is priority functional group and is part of the core name: x-alkanol
- Choose longest carbon chain that has the OH attached
- Remember to number!
- The oxygen itself does <u>not</u> count as a number

B. Cycloalkanols: The OH-carbon is automatically Number 1

C. <u>x-Alken-z-ol</u>. When an alkene is in the main carbon chain, you need two number descriptors, one for the alkene, the second for the alcohol.

- The OH still dictates the numbering
- The OH number gets moved right before the "ol"
- The alkene number goes in front, in front of the "alken" portion
- Note: you only put the OH number right in front of the "ol" when you have an alkenol (or alkynol)

OH

D. Diols: x,y-alkanediol

E. Functional Group Priority:  $CO_2H > C=O > OH > amine > alkene > halide$ 

OH

- When you have more than one functional group, the higher priority dictates the numbering
- The higher priority is used in the "core name"
- The lower priority group may be forced to be named as a substituent
- F. OH as a Substituent: "Hydroxy"

G. Common Names: Alkyl alcohol

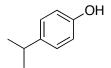

CH<sub>3</sub>OH

ОН

OH

- H. Substituted Phenols
  - IUPAC: use numbers, with OH carbon #1
  - Common:
    - o Ortho: 2-position, adjacent
    - Meta: 3-position, two carbons away
    - Para: 4 position
  - Skill: be able to use or recognize either system

IUPAC:

Common:

10.4 Physical Properties: Dominated by H-Bonding

BP: Match the boiling point for the following structures: 35°, 137°, 187°

OH

Θ

Water solubility: water solubility decreases as hydrophobic R gets longer

- In general,
  - $\circ$  R  $\leq$  4 carbons, ROH substantially water soluble
  - $\circ$  R  $\geq$  5 carbons, ROH minimal water solubility

#### 10.5 Commercially Important Alcohols

• Toxic: All alcohols are "toxic" if swallowed in sufficient quantities

CH <sub>3</sub> OH	∕∩он	OH	
• Cheap	• 200 mL (7 oz) $\rightarrow$ death	Rubbing alcohol	
• Solvent	<ul> <li>Least toxic alcohol</li> </ul>	• 100 mL $\rightarrow$ death	
• Fuel	<ul> <li>Alcoholic beverages</li> </ul>	• Kills germs on skin, but	
• 100 mL $\rightarrow$ death	Fermentation	not absorbed	
• 15 mL $\rightarrow$ blindness	• Solvent		

10.6 Acidity of Alcohols and Phenols

A. Alcohols are weak acids  $\rightarrow$  can be ionized by stronger bases

$$ROH + B^{\bigcirc} \implies RO^{\bigcirc} + BH$$

goes to the right (alkoxide) only if RO 
$$\bigcirc$$
 is more stable than B

• ex. 
$$\bigcirc$$
 NH<sub>2</sub>,  $\bigcirc$  CH<sub>3</sub>

• ex. If a less stable oxygen anion can convert to a more stable oxygen anion

 $\frown$ 

#### B. Acidity Table

Class	Structure	<u>Ka</u>	<u>Acid</u> Strength	<u>Anion</u>	<u>Base</u> Strength
Strong Acids	H-Cl	10 <sup>2</sup>		cl⊖	
Carboxylic Acid	R OH	10-5		R <sup>→</sup> O⊖	
Phenol	ОН	10 <sup>-10</sup>			
Water	H <sub>2</sub> O	10 <sup>-16</sup>		$_{\rm HO} \ominus$	
Alcohol	ROH	10-18		RO <sup>(C)</sup>	
Amine (N-H)	RNH <sub>2</sub>	10 <sup>-33</sup>		RNH⊖	
Alkane (C-H)	RCH <sub>3</sub>	10 <sup>-50</sup>		$\operatorname{RCH}_2 \ominus$	

Notes/skills:

- 1. Be able to rank acidity.
- 2. Memorize/understand neutral OH acidity ranking:  $RCO_2H > H_2O > ROH$ 
  - Reason: **resonance** stabilization of the **anion**
- 3. Predict deprotonation (acid/base) reactions
  - Any weak acid <u>will be</u> deprotonated by a <u>stronger base (lower</u> on table)
  - Any weak acid will not be deprotonated by a weaker base (higher on table)
- 4. Predict ether/water extraction problems
  - If an organic chemical is neutral and stays neutral, it will stay in ether layer
  - If an organic chemical is ionized (by an acid-base reaction), it will extract into the aqueous layer

Problems

8. Draw arrow to show whether equilibrium favors products or reactants. (Why?)

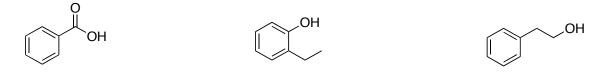

$$\Theta_{OH + H} \longrightarrow \Theta_{OH} \qquad H_2O + H_2O = H_2O + H_2O = H_2O =$$

9. Which of the following will deprotonate methanol?

$H_2O$	CH <sub>3</sub> CO <sub>2</sub> Na	PhONa	NaOH	NaNH <sub>2</sub>	CH <sub>3</sub> MgBr
--------	------------------------------------	-------	------	-------------------	----------------------

An acid (left side) will only be deprotonated by an anion/base that is **lower** on the right side

10. When the following are dissolved in ether and then treated with NaOH/water, which would extract out of the ether layer into the water layer?

10.6B Formation of Sodium, Potassium Alkoxides; 2-Step Conversion of Alcohols into Ethers via the Alkoxides

1	$ \begin{array}{ccc} R-OH & \xrightarrow{Na} & R-ONa \\ & & & \\ R-OH & \xrightarrow{K} & R-OK \end{array} \end{array} $	<ul> <li>Potassium (K) analogous.</li> <li>Key way to convert alcohol to alkoxide, reactive as S<sub>N</sub>2 nucleophile and E2 base.</li> </ul>
2	$R-OH \xrightarrow{1. \text{ Na}} R-O-R'$ 2. R'-X	<ul> <li>Alkoxide formation-S<sub>N</sub>2 route to ether</li> <li>The electrophile R'-X must be S<sub>N</sub>2 reactive, preferably 1° with a good leaving group</li> </ul>

Reaction 1: Key source of nucleophilic/basic alkoxides

1. BH <sub>3</sub> -THF	3. Na	
2. NaOH, H <sub>2</sub> O <sub>2</sub>	4. CH <sub>3</sub> CH <sub>2</sub> Br	

10.7 Synthesis of Alcohols: Review: See p. 2, from Alkyl Halides (S<sub>N</sub>2) and Alkenes

10.8 Organometallics: RM (M = Metal) = R  $\bigcirc$  M  $\oplus$ 

 $\begin{array}{ccc} \mathsf{R}-\mathsf{Br} & & \overset{\mathsf{Mg}}{\longrightarrow} & \mathsf{R}\mathsf{Mg}\mathsf{Br} \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ \mathsf{B}-\mathsf{Br} & & \overset{\mathsf{2Li}}{\longrightarrow} & \mathsf{Bl}\,\,i+\mathsf{Li}\mathsf{Br} \end{array}$ 

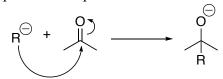

- 1. We will focus on the magnesium reagents RMgBr
- 2. RMgBr = "Grignard Reagents" (Victor Grignard)
- 3. Key: This is the way to make  $R^{\bigcirc}$ , strong nucleophiles/bases
- 4. RMgBr are formed via redox reaction.
  - Mg gives up two electrons, is oxidized
  - Bromine is reduced to bromide anion
  - Carbon is reduced to carbanion

$$\overset{\bigcirc}{\mathsf{R}} - \mathsf{Br}' + \overset{\bullet}{\mathsf{Mg}} \longrightarrow \mathsf{R}^{\bullet} + \overset{\bigcirc}{\mathsf{Br}} + \overset{\bigcirc}{\mathsf{Mg}^{\bullet}} \longrightarrow \overset{\bigcirc}{\mathsf{R}^{\bullet}} + \overset{\bigcirc}{\mathsf{Br}} + \overset{2+}{\mathsf{Mg}^{\bullet}}$$
 Not for Test

- 5. The formation of Grignard Reagents is completely general for all R-Halides:
  - 3°, 2°, and 1° alkyl halides all work well
  - Aryl and Vinyl halides as well as alkyl halides work well
  - RCl, RBr, and RI all work well
  - For class, we will normally use bromides, due to synthetic accessibility

### 6. <u>View as carbanions: $RMgBr = R \bigcirc$ Super Strong Bases and Nucleophiles</u>

- The counterion metal is a spectator
- Stability-reactivity principle: very unstable  $\rightarrow$  very reactive
- This great reactivity is very useful (as nucleophile)
- This great reactivity (as base) has implication for proper technical use (see following)
- 7. Solvent and handling: Grignard reactants RMgBr must be made, stored, and handled in special solvents under special conditions:
  - No water allowed
    - $R^{\bigcirc} + H_2O \rightarrow R-H + HO^{\bigcirc}$  Destroys carbanion
  - No alcohol or amines or acids allowed either, or carbanion will just deprotonate them too
  - If any chemicals with carbonyls are present, they too will react with the carbanion by nucleophile/electrophile reaction

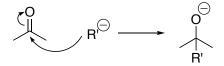

- Grignards and other organometallics are made in either alkane or ether solvents.
  - These don't have any acidic hydrogens that protonate carbanions.
  - These don't have any carbonyls that react with carbanions

#### 8. Two perspectives for dealing with organometallics in general and RMgBr in particular

- Mechanistic Thinking:  $R \ominus$
- Predict-the-product thinking: R-MgBr: easier to see source and substitution product.

 $R-Br \xrightarrow{Mg} R-MgBr \xrightarrow{Electrophile} R-Electrophile$ 

#### 10.9 Addition of RMgBr to Carbonyl Compounds: Alcohols are Produced

Carbonyl is strongly electrophile

1. Breakable  $\pi$  bond 2. Carbonyl polarity

-much stronger even than a 1° alkyl iodide!

- Exothermic Addition of Carbon or Hydrogen Anions:
  - σ bond (made) stronger than π bond (broken)
    oxygen anion more stable than carbanion

 $\overset{\mathsf{O}^{\delta^{-}}}{\overset{\overset{\overset{\phantom{}}}{\overset{\phantom{}}}}{\overset{\phantom{}}}} \longleftrightarrow \overset{\mathsf{O}^{\bigcirc}}{\overset{\overset{\phantom{}}}{\overset{\phantom{}}}}$ 

Additions of Grignard Reagents to Carbonyl Compounds From Carbonyl's Perspective From Grignard's Perspective  $\begin{array}{c} 1. \ H_2CO \\ R'MgBr \\ 2. \ H_3O^+ \end{array}$  $H \stackrel{O}{\longrightarrow} H \xrightarrow{1. R'MgBr} H \xrightarrow{OH} H \xrightarrow{H} H$ 1 carbon Mech сон R'× 4 chain 1º alcohol extension 2° alcohol formaldehyde R'MgBr  $\xrightarrow{1. \text{ RCHO}}_{2. \text{ H}_3\text{O}^+}$   $\xrightarrow{\text{R}}_{2^\circ \text{ alcohol}}^{\text{R}}$  $\begin{array}{c} \overbrace{H} \\ R \\ aldehyde \end{array} \begin{array}{c} 1. R'MgBr \\ \hline 2. H_3O^+ \\ \end{array} \begin{array}{c} OH \\ R \\ \hline R \\ H \end{array}$ Mech 5 2º alcohol  $R \stackrel{\checkmark}{\xrightarrow{}} R" \xrightarrow{1. R'MgBr} OH$ ketone  $R \stackrel{\sim}{\xrightarrow{}} R" \xrightarrow{2. H_3O^+} R \stackrel{OH}{\xrightarrow{}} R''$ R'MgBr  $\xrightarrow{1. R(R'')CO}_{2. H_3O^+}$ All three Mech 6 R groups can be 3° alcohol different. 3º alcohol At least 2 Mech R'MgBr  $\xrightarrow{1. \text{RCO}_2\text{R}}$   $\xrightarrow{\text{R'}}$   $\xrightarrow{\text{R'}}$   $\xrightarrow{\text{R'}}$ 7 R groups must be ester the same 3° alcohol (or carbonyl chloride)

Pattern:

- 1. After reaction, the original carbonyl carbon will have one and only one C-O single bond
- 2. For formaldehyde, aldehydes, and ketones, one R group adds (reactions 4-6)
- 3. For esters or carbonyl chlorides ("acid chlorides"), two R groups add
- Replace not only the carbonyl p-bond, but also the "extra" C-O or C-Cl single bond 4. Product output:
  - Formaldehyde (2 H's)  $\rightarrow$  1° alcohol
  - Aldehyde (1 H)  $\rightarrow$  2° alcohol
  - Ketone (0 H)  $\rightarrow$  3° alcohol. No need for all 3 attachments to be the same.
  - Ester (0 H)  $\rightarrow$  3° alcohol. At least two common attachments at end.

#### Predicting Grignard Reaction Products

- 1. From carbonyl perspective:
  - The carbanion R' adds to the carbonyl carbon
  - The carbonyl =O gets replaced by -OH
  - For formaldehyde, aldehydes, and ketones: the two attachments on the original carbonyl carbon remain attached as spectators
  - For esters or acid chlorides: the one non-heteroatom attachment on the original carbonyl carbon remain attached as spectators.
    - The "extra" heteroatom gets replaced by a second carbanion R'
- 2. From Grignard perspective:
  - Where R-MgBr begins, R-C-OH ends.
    - In other words, the MgBr gets replaced by the carbonyl carbon

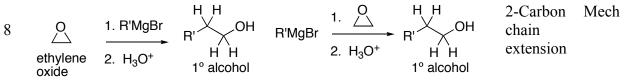

Note: Be sure that in the product, no carbon has more than one C-O bond

Draw products from the following reactions.

$$1 \qquad \underbrace{1}_{Q} \qquad \underbrace{1}_$$

1°, 2° or 3°?

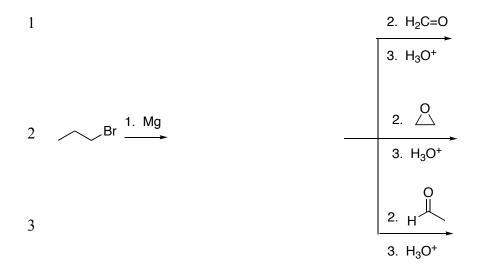

10.9E Grignard Reaction with Ethylene Oxide (Simplest Epoxide)

Notes

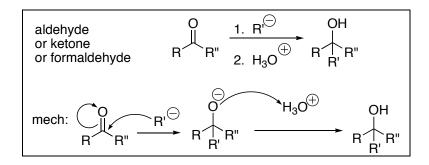

- 1. Results in a 1° Alcohol
- 2. Predicting product: Two carbons end up in between the carbanion R' and the OH
- 3. Ethylene oxide and formaldehyde are complementary Grignard acceptors leading to 1° alcohols
  - Ethylene oxide extends the carbon chain by two (relative to the original RMgBr)
  - Formaldehyde extends the carbon chain by one (relative to the original RMgBr)
- 4. 2-Carbon ethylene oxide and 2-carbon ethanal give different products
  - $\circ$  Ethylene oxide  $\rightarrow$  the OH is 1° and the OH is two carbons removed from the carbanion R
  - Ethanal → the OH is 2° and the OH and carbanion R are both connected to the same carbon

Draw products from the following reactions.

#### **Reaction Mechanisms for Grignard Reactions**

Formaldehyde, Aldehyde, or Ketone as Carbonyl Compound (Reactions 4, 5, and 6)

- 1. Two simple steps:
  - a. <u>Addition</u>

#### b. <u>Protonation</u>

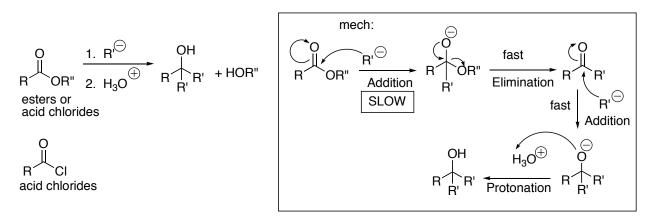

- 2. Timing:
  - a. The carbanion is added first, at one step in time, under strongly anionic conditions
  - b. Later acid is added, in a second laboratory step. This provides a cationic environment
- 3. RMgBr = R-MgBr = R  $\bigcirc$  carbanion
  - a. The <sup>(+)</sup> MgBr stuff is spectator, doesn't need to be drawn in
  - b. Ignore in mechanisms
  - c. In reality, it actually does play a nontrivial role, but we'll save that for grad school!

Draw mechanisms for the following reactions:

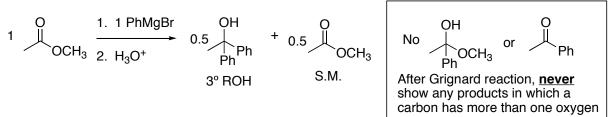

$$1 \qquad \overset{O}{\underset{1}{\overset{\parallel}{\overset{\parallel}{\overset{\phantom{\parallel}}}}}} \qquad \underbrace{1. \ PhMgBr}{2. \ H_3O^+}$$

$$2 \qquad 0 \qquad 1. \qquad MgBr \\ \qquad \swarrow H \qquad 2. \qquad H_3O^+$$

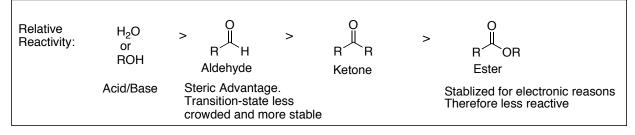

#### Esters or Acid Chlorides: More Complex, Needs to Explain Two Additions and More Bond Breakings

- 1. Four Step Mechanism:
  - a. Addition
  - b. Elimination
  - c. Addition
  - d. **Protonation**
- 2. Timing:
  - a. The carbanion is added first, at one point in time, under strongly anionic conditions
     The first three steps all occur under these anionic conditions
  - b. Acid is only added much later, in a second laboratory step. This gives a cationic environment.
  - c. Why don't you just protonate after the first step?
    - There is no proton source available, and the elimination proceeds instead!
- 3. What if I add only one RMgBr?

#### Why? Kinetics and Reactivity. MEMORIZE.

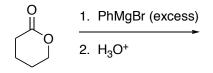

- Large differences in reactivity, with ketone > ester
- Elimination step 2 is also very fast
- Thus, under the anionic conditions, the addition is the slow step
  - After it does happen, elimination and another addition happens bang-bang.

Draw Mechanism:

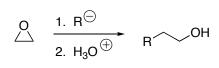

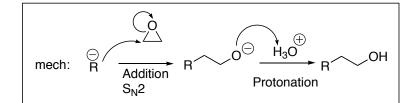

<u>Cyclic Ester:</u> The O-Carbonyl single bond breaks, but the other C-O single bond does <u>not</u> break -the result is formation of a dialcohol

Draw product and mechanism for the following:

#### **Ethylene Oxide Mechanism**

Draw product and mechanism for the following:

$$MgBr \xrightarrow{1.} 0 \\ 2. H_3O^{\oplus}$$

## More Grignard Practice. Including polyfunctional Molecules: (Know relative reactivity)

$$1 \qquad H_{3}CO \qquad 0 \qquad 1. PhMgBr (excess)$$

$$2 \qquad H_{3}CO \qquad 0 \qquad 1. PhMgBr (1.0 equivalent)$$

$$2 \qquad H_{3}CO \qquad 0 \qquad 1. PhMgBr (1.0 equivalent)$$

$$3 \qquad H_{3}CO \qquad 0 \qquad 1. PhMgBr (1.0 equivalent)$$

$$3 \qquad H_{3}CO \qquad 0 \qquad H \qquad 1. PhMgBr (1.0 equivalent)$$

$$4 \qquad Ph \qquad H \qquad 1. \qquad MgBr$$

$$2 \qquad H_{3}O^{+}$$

$$7 \qquad 0 \qquad H \qquad 1. \qquad H_{3}O^{+}$$

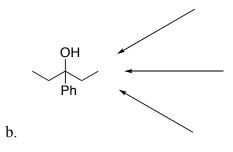

$$8 \qquad BrMg \qquad 1. \qquad Ag^{+}$$

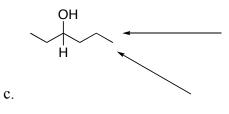

$$8 \qquad BrMg \qquad 1. \qquad Ag^{+}$$

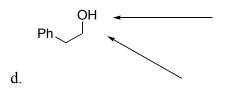

Grignards in Synthesis: Provide Precursors.

- Think backwards from Targets to Reactants. •
- Identify possible Grignards and Grignard acceptors
- Pattern:
  - 3° alcohol, all three attachments different ← Ketone Precursor 3° alcohol, two (or more) of the attachments identical ← Ester •
  - •
  - •
  - 2° alcohol ← Aldehyde 1° alcohol ← Formaldehyde or ethylene oxide •

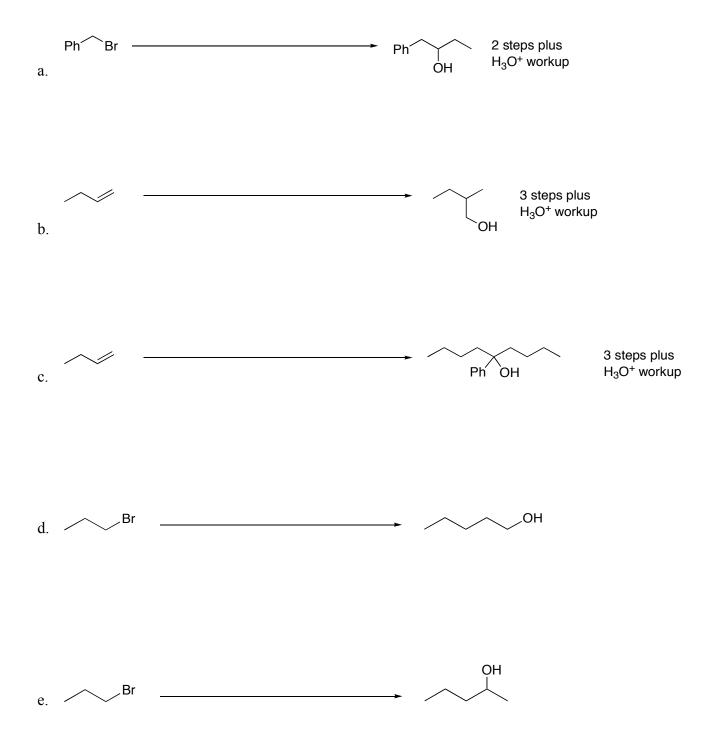

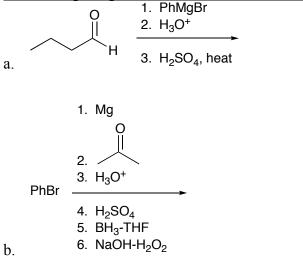

<u>Provide Reagents for the Following Transformations.</u> You may use whatever reagents, including ketones or aldehydes or Grignards or esters, that you need.

- Key: Try to identify key C-C connection in the product that wasn't present to start with
- Try to identify the where the reactant carbons are in the final product
- Numbering your carbon chains is very helpful.
- Usually best to work backwards from the product

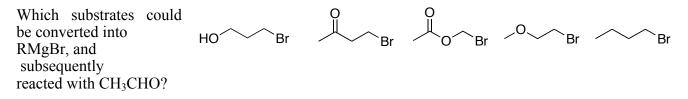

10.10 Restrictions on Grignard Reactions

- RMgBr = R  $\bigcirc$  carbanion, highly unstable, highly reactive.
- Unstable in the presence of:
  - 1. OH's (get proton transfer reaction)
  - 2. Carbonyls (get Grignard-type nucleophilic addition)
- 1. Solvent limitations. RMgBr cannot be formed and used in the presence of
  - H2O
  - ROH
  - Any solvent with a C=O

Which Solvents (if any) o ↓ ∧ Would be OK for ЮΗ Handling RMgBr?,

2. Substrate limitations. Any organohalide that also contains an OH or C=O bond can't be converted into a useful RMgBr, because it will self-destruct.

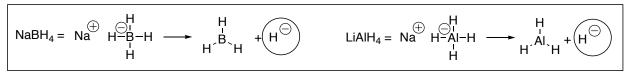

- 3. Atmosphere/Glassware/Storage limitations. Make, store, and use in:
  - water-free dried glassware
  - moisture-free atmosphere. (Dried air, or else under nitrogen or argon atmosphere)
  - When stored for extended periods, must have very good seals so that no air can leak in.

10.11 Alcohols by Reduction of Carbonyls:  $H ^{\bigcirc}$  Addition

9 
$$\bigcap_{R \to H}^{\circ} \frac{NaBH_{4}}{CH_{3}OH}$$
 or  $\frac{1. LiAH_{4}}{2. H_{3}O^{+}}$   $\bigcap_{R \to H}^{\circ} \frac{H}{H}$   $H_{1^{\circ} alcohol}$   
10  $\bigcap_{R \to R^{\circ}}^{\circ} \frac{NaBH_{4}}{CH_{3}OH}$  or  $\frac{1. LiAH_{4}}{2. H_{3}O^{+}}$   $\bigcap_{R^{\circ}}^{\circ} \frac{H}{R}$   $H_{R}^{\circ}$   
 $R^{\circ} R^{\circ} \frac{1. LiAH_{4}}{CH_{3}OH}$   $OH$   $R^{\circ} \frac{H}{R}$   $H_{R}^{\circ}$   $R^{\circ} R^{\circ}$   $R^{\circ} H_{R}^{\circ}$   $R^{\circ} R^{\circ}$   $R^{\circ} R^{\circ}$   $R^{\circ} R^{\circ}$   $R^{\circ} R^{\circ}$   $R^{\circ} R^{\circ}$   $R^{\circ} R^{\circ} R^{\circ}$   $R^{\circ} R^{\circ} R^{\circ}$   $R^{\circ} R^{\circ} R^{$ 

#### Notes:

- Mechanisms are exactly like with Grignard reactions
- LiAlH<sub>4</sub> and NaBH<sub>4</sub> function as hydride anions H  $\bigcirc$
- For mechanisms, just draw  $H^{\bigcirc}$  rather than trying to involve the Li and Al and Na and B...

- Boron is one row higher than aluminum, and in keeping with normal periodic patterns is more electronegative
  - $\circ\,$  Because boron is more electronegative, the  $BH_4\,^{\bigcirc}\,$  anion is more stable, and less reactive.
    - The boron holds the  $H^{\bigcirc}$  more tightly.
  - Aluminum being less electronegative doesn't attract and hold the H  $^{\bigcirc}$  as well, and thus is considerably more reactive.

Reactivity

	Aldehydes	Ketones	Esters
LiAlH <sub>4</sub>	Yes	Yes	Yes
NaBH <sub>4</sub>	Yes	Yes	No

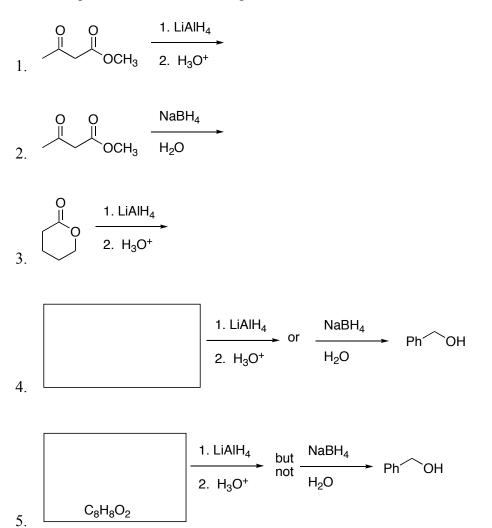

#### LiAlH<sub>4</sub> is much stronger, NaBH<sub>4</sub> much weaker

- 1. LiAlH<sub>4</sub> is strong enough to react with esters, NaBH<sub>4</sub> isn't
- 2. <u>Selective reduction</u>: if both an ester and an aldehyde/ketone are present:
  - LiAlH<sub>4</sub> reduces both
  - NaBH<sub>4</sub> selectively reduces the aldehyde/ketone but leaves the ester untouched
- 3. LiAlH<sub>4</sub> is strong enough to react with and be destroyed by water or alcohol; NaBH<sub>4</sub> isn't

$$LiAlH_4 + H_2O \rightarrow H_2(gas) + LiOH + AlH_3 + heat$$

- a. As a result, LiAlH<sub>4</sub> is harder to use and store
- b. Acid has to be added in a subsequent step with the LiAlH<sub>4</sub>; (thus, 2-step recipe)
- c. NaBH<sub>4</sub> can be run in alcohol solvent which serves as a proton source for protonating alkoxide
- d. Solvent restrictions, glassware must be dry, wet air must be excluded, etc.
- e. Because NaBH<sub>4</sub> is stable to water, it's easier to handle in air, easier to store, much easier to work with
- f. Default: for a simple aldehyde or ketone reduction, normally use NaBH<sub>4</sub> because it's so much easier
- 4. LiAlH<sub>4</sub> is strong enough to react with esters,  $NaBH_4$  isn't

Draw the products for the following reactions.

Draw the mechanism for the following reaction.

6.  

$$Ph \xrightarrow{H} H \xrightarrow{NaBH_4} OH$$
  
 $GH_3OH \xrightarrow{OH} Ph \xrightarrow{OH} Ph$   
 $1. \text{ LiAlH}_4$   
 $2. \text{ H}_3O$
